### 9.4.1

Advice June 2011

## ECOREGION STOCK

## Advice for 2012

ICES advises on the basis of the transition to the MSY approach that landings in 2012 should be no more than 51900 t .

## Stock status

Figure 9.4.1.1
Hake in Division IIIa, Subareas IV, VI, and VII, and Divisions VIIIa,b,d. Summary of stock assessment: landings, recruitment, F, and SSB over the years.

The spawning biomass has been increasing since 1998 and is estimated to be record high in 2011.Fishing mortality has been decreasing in recent years, but is still above $\mathrm{F}_{\text {MSY }}$. Recruitment fluctuations appear to be without substantial trend over the whole series. After several high recruitments in 2006 to 2008, the last two recruitments are estimated to be low.

## Management plans

A recovery plan has been agreed by the EU in 2004 (EC Reg. No. 811/2004). The aim of the plan is to increase the SSB to above 140000 t with a fishing mortality ( $\mathrm{F}_{\mathrm{MP}}$ ) of 0.25 , constrained by a year-to-year change in TAC of $15 \%$ when SSB is above 100000 t .

## Biology

European hake is widely distributed over the Northeast Atlantic shelf. Although, there is no clear evidence of multiple populations in the Northeast Atlantic, ICES assumes two different stock units. The Northern stock is distributed over a wide area. There are two major nursery areas: in the Bay of Biscay and off southern Ireland. Hake growth is now known to be faster than previously estimated.

## The fisheries

Hake is caught in mixed fisheries together with megrim, anglerfish, and Nephrops. Discards of juvenile hake can be substantial in some areas and fleets. An important increase in landings has occurred in the northern part of the distribution area (Division IIIa, and Subareas IV and VI) in recent years. Since the introduction of the high vertical opening trawls in the mid-1990s, no significant changes in fishing technology have been introduced.

Catch by fleet Total landings (2010) $=73 \mathrm{kt}(31 \%$ trawl, $20 \%$ gillnet, $29 \%$ longline, and $21 \%$ unspecified gears); discards 6.7 kt (underestimated, only estimated and assumed for part of the trawl fleets).

## Quality considerations

This stock was benchmarked in 2010 and now the assessment is carried out using a length-based model (without age data, as no age-reading criterion exists at present). For this year's assessment, the modelled time period has been extended back to 1978. This provides a clearer perspective of the historical development of the stock and has improved the quality of the assessment. The uncertainty of SSB and F estimates is lower. The current assessment suffers from some shortage of tuning data, particularly in relation to earlier years, for areas outside VII and VIII and the larger individuals in the population.

Figure 9.4.1.2 Hake in Division IIIa, Subareas IV, VI, and VII, and Divisions VIIIa,b,d. Historical assessment results (final year recruitment estimates included). F is based on lengths $15-80 \mathrm{~cm}$, corresponding to approximately $1-5$ years old; in previous assessment years the F age range was $2-6$ years old.

## Scientific basis

| Assessment type | Length-based model (SS3). |
| :--- | :--- |
| Input data | Four survey indices (EVHOE-WIBTS-Q4, SpPGFS-WIBTS-Q4, IGFS-WIBTS-Q4, |
|  | RESSGASC) . |
| Discards and bycatch | Discards included in the assessment. |
| Indicators | None. |
| Other information | This stock was benchmarked in 2010 (WKROUND). |

## Management plan(s)

Due to the new perspective of historical stock trends, resulting from the new assessment, the previously defined precautionary reference points are no longer appropriate. In particular, the absolute levels of spawning biomass, fishing mortality, and recruitment have shifted to different scales. As a consequence, the TAC corresponding to the current recovery plan (EC Reg. No. 811/2004) should not be considered, because the plan uses target values based on precautionary reference points that are no longer appropriate.

## MSY approach

The stock is considered to be above any potential MSY $\mathrm{B}_{\text {trigger }}$. Following the ICES MSY framework implies fishing mortality to be reduced to 0.24 , resulting in landings of 39400 tonnes in 2012. This is expected to lead to an SSB of 138000 tonnes in 2013.

Following the transition scheme towards the ICES MSY framework implies fishing mortality be reduced to 0.33 and corresponding to landing of 51900 tonnes. This is expected to lead to an SSB of 125000 tonnes in 2013.

## Additional considerations

Discards of juvenile hake can be substantial in some areas and fleets. The spawning biomass and the long-term yield can be substantially improved by reducing mortality of small fish. This could be achieved by measures that reduce unwanted bycatch through shifting the selection pattern towards larger fish.

The application of a new assessment method has resulted in a change in the perception of the historical stock. Thus, the previous defined precautionary reference points, on which the recovery plan is based, are no longer appropriate.

Hake in the ICES area is managed and assessed as two separate stocks. There is no biological basis for the current ICES stock definition of northern and southern hake. These stocks have similar biology with an unknown degree of mixing.

## Quality considerations

Last year, the assessment was found to be limited in its ability to precisely estimate current stock abundance and mortality. This was mainly due to the time period, 1990-2009, which did not exhibit strong contrasts in the available data and little information was available on large fish. All this led to large uncertainties associated with the main population parameters (SSB, F, and recruitment), particularly regarding the rate of decrease in F and increase in SSB in the most recent years. This year, the time period has been extended back to 1978. This has improved the model's ability to determine the degree to which various levels of fishing reduced hake abundance during the mid-1980s and the 1990s and thus provides a clearer perspective of the historical development of the stock.

The assessment is now carried out with discards included. There is large uncertainty associated with estimation of discards, which is reflected in the projected discard values.

## Management considerations

The fast growth rate and the assumed high natural mortality generates a more rapid turn-over of the hake stock dynamics than previously assumed. This means that short-term projections of SSB and landings are more sensitive to variations in recruitment. The short-term forecasts of SSB and yield obtained this year are influenced by the low recruitment estimates for 2009 and 2010.

## Comparison with previous assessment

Last year's assessment was indicative of trends. This year's assessment is consistent with last year's F and SSB trends.
The basis for the advice is the same as last year.
